Writing a Slice Definition

The first step in writing any Ice application is to write a Slice definition containing the interfaces that are used by the application. For our minimal printing application, we write the following Slice definition:

```
Module Demo {
   interface Printer {
      void printString(string s);
   };
};
```

We save this text in a file called Printer.ice.

Our Slice definitions consist of the module <code>Demo</code> containing a single interface called <code>Printer</code>. For now, the interface is very simple and provides only a single operation, called <code>printString</code>. The <code>printString</code> operation accepts a string as its sole input parameter; the text of that string is what appears on the (possibly remote) printer.
