Using a Freeze Evictor in the File System Server

In this section, we present file system implementations that use a transactional evictor. The implementations are based on the ones discussed in Obje ct Life Cycle, and in this section we only discuss code that illustrates use of the Freeze evictor.

In general, incorporating a Freeze evictor into your application requires the following steps:

- 1. Evaluate your existing Slice definitions for a suitable persistent object type.
- If no suitable type is found, you typically define a new derived class that captures your persistent state requirements. Consider placing these
 definitions in a separate file: they are only used by the server for persistence, and therefore do not need to appear in the "public" definitions
 required by clients. Also consider placing your persistent types in a separate module to avoid name clashes.
- 3. If you use indexes with your evictor, generate code (using slice2freeze or slice2freezej) for your new definitions.
- 4. Create an evictor and register it as a servant locator with an object adapter.
- 5. Create instances of your persistent type and register them with the evictor.

Persistent Types for File System Evictor

Fortunately, it is unnecessary for us to change any of the existing file system Slice definitions to incorporate the Freeze evictor. However, we do need to add metadata definitions to inform the evictor which operations modify object state:

Slice

```
module Filesystem {
    // ...
    interface Node {
        idempotent string name();
        ["freeze:write"]
        void destroy() throws PermissionDenied;
    };
    // ...
    interface File extends Node {
        idempotent Lines read();
        ["freeze:write"]
        idempotent void write(Lines text) throws GenericError;
    };
    // ...
    interface Directory extends Node {
        idempotent NodeDescSeq list();
        idempotent NodeDesc find(string name) throws NoSuchName;
        ["freeze:write"]
        File* createFile(string name) throws NameInUse;
        ["freeze:write"]
        Directory* createDirectory(string name) throws NameInUse;
    };
};
```

These definitions are identical to the original ones, with the exception of the added ["freeze:write"] directives.

The remaining definitions are in derived classes:

Slice

```
#include <Filesystem.ice>
module Filesystem {
   class PersistentDirectory;
   class PersistentNode implements Node {
        string nodeName;
        PersistentDirectory* parent;
    };
   class PersistentFile extends PersistentNode implements File {
        Lines text;
    };
   dictionary<string, NodeDesc> NodeDict;
   class PersistentDirectory extends PersistentNode implements Directory {
        ["freeze:write"]
        void removeNode(string name);
        NodeDict nodes;
    };
};
```

As you can see, we have sub-classed all of the file system interfaces. Let us examine each one in turn.

The PersistentNode class adds two data members: nodeName and parent.

We used nodeName instead of name because name is already used as an operation in the Node interface.

The file system implementation requires that a child node knows its parent node in order to properly implement the destroy operation. Previous implementations had a state member of type DirectoryI, but that is not workable here. It is no longer possible to pass the parent node to the child node's constructor because the evictor may be instantiating the child node (via a factory), and the parent node will not be known. Even if it were known, another factor to consider is that there is no guarantee that the parent node will be active when the child invokes on it, because the evictor may have evicted it. We solve these issues by storing a proxy to the parent node. If the child node invokes on the parent node via the proxy, the evictor automatically activates the parent node if necessary.

The PersistentFile class is very straightforward, simply adding a text member representing the contents of the file. Notice that the class extends PersistentNode, and therefore inherits the state members declared by the base class.

Finally, the PersistentDirectory class defines the removeNode operation, and adds the nodes state member representing the immediate children of the directory node. Since a child node contains only a proxy for its PersistentDirectory parent, and not a reference to an implementation class, there must be a Slice-defined operation that can be invoked when the child is destroyed.

If we had followed our earlier advice, we would have defined Node, File, and Directory classes in a separate PersistentFilesystem module, but in this example we use the existing Filesystem module for the sake of simplicity.
