

Server-Template Descriptor Element

A `server-template` element defines a [template](#) for a `server` element, simplifying the task of deploying multiple instances of the same server definition. The template should contain a parameterized `server` element that is instantiated using a `server-instance` element.

This element may only appear as a child of an [application](#) element.

The following attributes are supported:

Attribute	Description	Required
<code>id</code>	Specifies the identifier for the server template. This identifier must be unique among all server templates in the application.	Yes

A template may declare [parameters](#) that are used to instantiate the `server` element. You can define a default value for each parameter. Parameters without a default value are considered mandatory and values for them must be supplied by the `server-instance` element.

Here is an example to demonstrate the use of this element:

XML
<pre><icegrid> <application name="SampleApp"> <server-template id="ServerTemplate"> <parameter name="id"/> <server id="\${id}" activation="manual" .../> </server-template> <node name="Node1"> <server-instance template="ServerTemplate" id="TheServer" /> </node> </application> </icegrid></pre>
