Inheritance Hierarchy for Exceptions in PHP

The mapping for exceptions is based on the inheritance hierarchy shown below:

The ancestor of all exceptions is <code>Exception</code>, from which <code>Ice_Exception</code> is derived. <code>Ice_LocalException</code> and <code>Ice_UserException</code> are derived from <code>Ice_Exception</code> and form the base for all run-time and user exceptions.

PHP Mapping for User Exceptions

Here is a fragment of the Slice definition for our world time server once more:

```
exception GenericError {
    string reason;
};
exception BadTimeVal extends GenericError {};
exception BadZoneName extends GenericError {};
```

PHP

```
class GenericError extends Ice_UserException
{
    public function __construct($reason='');
    public function ice_name();
    public function __toString();

    public $reason;
}

class BadTimeVal extends GenericError
{
    public function __construct($reason='');
    public function ice_name();
    public function __toString();
}

class BadZoneName extends GenericError
{
    public function __construct($reason='');
    public function __construct($reason='');
    public function __construct($reason='');
    public function ice_name();
    public function __toString();
}
```

Each Slice exception is mapped to a PHP class with the same name. The inheritance structure of the Slice exceptions is preserved for the generated classes, so BadTimeVal and BadZoneName inherit from GenericError.

Each exception member corresponds to an instance variable of the instance, which the constructor initializes to a default value appropriate for its type. You can also declare different default values for members of primitive and enumerated types.

Although BadTimeVal and BadZoneName do not declare data members, their constructors still accept a value for the inherited data member reason in order to pass it to the constructor of the base exception GenericError.

Each exception also defines the ice_name method to return the exception's type name, as well as the __toString magic method to return a stringified representation of the exception and its members.

All user exceptions are derived from the base class Ice_UserException. This allows you to catch all user exceptions generically by installing a handler for Ice_UserException. Similarly, you can catch all Ice run-time exceptions with a handler for Ice_LocalException, and you can catch all Ice exceptions with a handler for Ice_Exception.

PHP Mapping for Run-Time Exceptions

The Ice run time throws run-time exceptions for a number of pre-defined error conditions. All run-time exceptions directly or indirectly derive from Ice_LocalException (which, in turn, derives from Ice_Exception).

By catching exceptions at the appropriate point in the inheritance hierarchy, you can handle exceptions according to the category of error they indicate:

- Ice_LocalException
 This is the root of the inheritance tree for run-time exceptions.
- Ice_UserException
 This is the root of the inheritance tree for user exceptions.
- Ice_TimeoutException
 This is the base exception for both operation-invocation and connection-establishment timeouts.
- Ice_ConnectTimeoutException
 This exception is raised when the initial attempt to establish a connection to a server times out.

For example, Ice_ConnectTimeoutException can be handled as Ice_ConnectTimeoutException, Ice_TimeoutException, Ice_LocalException, or Ice_Exception.

You will probably have little need to catch run-time exceptions as their most-derived type and instead catch them as Ice_LocalException; the finegrained error handling offered by the remainder of the hierarchy is of interest mainly in the implementation of the Ice run time. Exceptions to this rule are the exceptions related to facet and object life cycles, which you may want to catch explicitly. These exceptions are Ice_FacetNotExistExcept ion and Ice_ObjectNotExistException, respectively.
