

Object Descriptor Element

An object element defines a [well-known object](#) in the IceGrid registry. Clients can refer to this object using only its identity, or they can search for well-known objects of a specific type.

This element may only appear as a child of an [adapter](#) element or a [replica-group](#) element.

The following attributes are supported:

Attribute	Description	Required
identity	Specifies the identity by which this object is known.	Yes
property	Specifies the name of a property to generate that contains the stringified identity of the object. This attribute is only allowed if this object element is a child of an adapter element.	No
type	An arbitrary string used to group objects. By convention, the string represents the most-derived Slice type ID of the object, but an application is free to use another convention.	No
proxy-options	The proxy options to use for the proxy of the well-known object return by IceGrid.	No

Here is an example to demonstrate the use of this element:

XML
<pre><adapter name="MyAdapter" id="WellKnownAdapter" ...> <object identity="WellKnownObject" type="::Module::WellKnownInterface" proxy-options="-o"/> </adapter></pre>

In the configuration above, the object can be located via the equivalent proxies `WellKnownObject` and `WellKnownObject@WellKnownAdapter`.
